# 3a. Allgemeine Software - ESP32

Wir verwenden auf dem ESP32 die Software ESPEasy, um die Sensor-Rohdaten auszulesen und per MQTT an den LoxBerry weiterzuleiten. Natürlich könnt ihr auch Tasmota oder ESPHome o. ä. verwenden. Ihr müsst dann aber darauf achten, dass die Daten exakt so im MQTT Broker eingeliefert werden, wie es das Weatherstation Plugin später erwartet! Auch die Zykluszeiten (also die Sendeintervalle) müssen identisch sein!

Dann gibt es noch einen Unterschied, ob ihr den Blitzsensor AS3935 verwenden wollt oder nicht. Wenn ihr den Blitzsensor benutzen wollt, müsst ihr die Firmware selbst kompilieren (oder unsere vorkompilierte, aber eventuell etwas ältere Firmware verwenden). Ohne Blitzsensor könnt ihr die aktuellen vorkompilierten Versionen von ESPEasy verwenden, was das Ganze erheblich vereinfacht. Aber auch das Selbstkompilieren ist keine Raketenwissenschaft mit etwas PC-Erfahrung - ich gebe Euch hier eine detaillierte Anleitung.

# Firmware ohne Blitzsensor AS3935

Folgende Software benötigt ihr:

• ESPEasy Firmware: https://github.com/letscontrolit/ESPEasy/releases

Zunächst ladet ihr Euch das neueste Release der Firmware herunter. Dieses findet ihr unter dem obigen Link unter "Assets". Wählt die Firmware aus, die für euren ESP32 passt - normaler die Standard-ESP32 Firmware, also z.B. ESPEasy\_mega\_20241222\_ESP32\_binaries.zip

Entpackt die Firmwarefiles mit einem ZIP-Programm in ein beliebiges Verzeichnis.

Das war's an dieser Stelle schon. Macht jetzt im Kapitel Firmware flashen weiter.

## Firmware mit Blitzsensor AS3935

Leider gibt es keine vorkompilierte Firmware mit ESPEasy, die alle von uns genutzten Sensoren beinhaltet. Deswegen muss die Firmware von uns selbst kompiliert werden. Keine Angst - so schwer ist das nicht. Wer es dennoch nicht hinbekommt, kann sich auch hier die von uns bereits kompilierte Firmware herunterladen. Diese ist vermutlich nicht mehr ganz neu, das macht aber in aller Regel gar nichts. So funktioniert einwandfrei. Download hier:

esp\_easy\_mega\_20241231\_custom\_esp32\_4m316k\_littlefs\_eth.zip

Die Datei muss noch mit einem ZIP-Programm in ein beliebiges Verzeichnis entpackt werden. Macht dann im Kapitel Firmware flashen weiter.

Wenn ihr die Firmware selbst kompilieren wollt, benötigt ihr folgende Software:

- ESPEasy Source Code: https://github.com/letscontrolit/ESPEasy/archive/refs/heads/mega.zip
- Microsoft Visual Code Studio: https://code.visualstudio.com/

Als erstes ladet ihr Euch den Sourcecode vom ESPEasy Projekt über obigen Link herunter und

entpackt diesen mit einem ZIP-Programm in ein beliebiges Verzeichnis.

Zunächst installiert ihr Microsoft Visual Code Studio auf eurem Rechner in startet es. Geht auf der linken Seite dann auf Extensions (der "kleine Würfel mit dem herausfliegenden Viertel" ganz unten). Nun sucht ihr der Reihe nach nach folgenden Extensions (über das Suchfeld) und installiert diese über den blauen Install Button:

- C/C++ Extension Pack (by Microsoft) installiert automatisch auch die Extension C/C++ mit
- PlatformIO IDE (by PlatformIO)

Die Installation dauert etwas - über ein kleines Fenster unten rechts könnt ihr jeweils den Status sehen. Nachdem die Installation durchgelaufen ist, müsst ihr VS Code einmal neu starten. Nun geht ihr in der rechten Leiste auf den Explorer und wählt den blauen Button Open Folder. Wechselt in das gerade eben entpackte Archiv mit dem Source Code. Ihr müsst das Verzeichnis auswählen, welches die Unterverzeichnisse src, lib, boards etc. enthält. Setzt den Haken bei Trust the author of all files in the parrent folder... und klickt auf Yes, ... Nun wird der Sourcecode von PlatformIO vorbereitet. Das dauert eine ganze Weile. Der Status wird Euch wieder unten rechts angezeigt.

Nun bereiten wir den Sourcecode für die spezifischen Einstellungen vor, die wir in der Firmware benötigen (u. a. wird hier festgelegt, welche Plugins und damit Sensoren in der Firmware zur Verfügung stehen). Dazu gehen wir links auf den Explorer und navigieren dann zur Datei src\Custom-Sample.h. Kopiert die Datei (Strg + C) und fügt sie anschließend an gleicher Stelle noch einmal ein (Strg + V). Benennt die neue Datei per rechter Maustaste um in Custom.h (Rename). Löscht den gesamten Inhalt in der Datei (Strg + a und Entf) und ersetzt ihn durch den Inhalt der folgenden Datei:

#### Custom.h

```
#ifndef ESPEASY CUSTOM H
#define ESPEASY CUSTOM H
/*
   To modify the stock configuration without changing the EspEasy.ino
file :
   1) rename this file to "Custom.h" (It is ignored by Git)
   2) define your own settings below
   3) define USE CUSTOM H as a build flags. ie : export
PLATFORMIO_BUILD_FLAGS="'-DUSE_CUSTOM_H'"
*/
/*
Your Own Default Settings
You can basically ovveride ALL macro defined in ESPEasy.ino.
   Don't forget to first #undef each existing #define that you add
below.
   But since this Custom.h is included before other defines are made,
vou don't have to undef a lot of defines.
   Here are some examples:
*/
// --- Feature Flagging ----
// Can be set to 1 to enable, 0 to disable, or not set to use the
default (usually via define_plugin_sets.h)
#define FEATURE RULES EASY COLOR CODE 1 // Use code highlighting,
autocompletion and command suggestions in Rules
#define FEATURE ESPEASY P2P
                                 1 // (1/0) enables the ESP
Easy P2P protocol

```

Mit Strg + S speichert ihr die Datei ab. Nun wählt ihr links im Menu PlatformIO aus (der kleine Alien ganz unten). Ihr seht eine lange Liste an sogenannten Tasks - das sind im Prinzip die einzelnen Firmwares, die kompiliert werden können. Alle Firmwares, die mit custom\_beginnen, nutzen die von uns gerade erstelle Custom.h Datei. Sucht Euch die Firmware für euren ESP32 heraus, also z. B. custom\_ESP32\_4M316k\_LittleFS\_ETH, und klappt diese nach unten auf (Achtung! Die liste ist nicht alphabetisch sortiert!). 4M steht hier übrigens für 4MB Flashspeicher und 316k für die Größe des Dateisystems, LittleFS für die Verwendung des effizienten LittleFS Dateisystems. VS Code fängt wieder an zu arbeiten - auch das dauert eine ganze Weile. Irgendwann ist er fertig und klappt zunächst euren zuvor aufgeklappten Menüpunkt wieder zu. Sucht ihn Euch neu aus der Liste und klappt ihn wieder auf. Ihr seht jetzt zahlreiche neue Menüpunkte darunter - und unter anderem auch den Build Menüpunkt. Klickt ihr dort drauf, wird die Firmware kompiliert. Das machen wir jetzt und warten wieder eine längere Zeit, bis die Firmware komplett kompiliert wurde. Im Terminal unten rechts seht ihr die Ausgabe des Kompilers. Es sollte alles ohne Abbruch/Fehler durchlaufen (einige Warnungen sind normal).

Die fertig kompilierte Firmware findet ihr im Verzeichnis build\_output\bin. Das **Factory**-File ist dabei gedacht für das erste Flashen (inkl. Bootloader), während das File ohne Factory im Namen für das OTA (Over-the-Air) Update dient.

Das war's an dieser Stelle - Du hast es geschafft! Macht jetzt im Kapitel Firmware flashen weiter.

### **Firmware flashen**

Folgende Software benötigt ihr:

- Flash Download Tool: https://docs.espressif.com/projects/esp-test-tools/en/latest/esp32/production\_stage/tools/flash\_d ownload\_tool.html
- PuTTY: https://www.putty.org/

Als erstes ladet ihr Euch noch die Flashsoftware "Flash Download Tool" herunter. Das Flash Download Tool wird auf euren Rechner mit einem ZIP-Programm entpackt. Jetzt verbindet ihr euren ESP32 per USB mit dem Rechner. Der ESP32 meldet sich als USB-to-UART Bridge CP210x oder FTDI am Rechner an. Sollte der Chip nicht erkannt werden, müsst ihr den entsprechenden Treiber noch installieren, siehe hier:

https://docs.espressif.com/projects/esp-idf/en/latest/esp32/get-started/establish-serial-connection.htm |

Überprüft nun, welcher COM-Port eurem Device zugeordnet wurde: https://docs.espressif.com/projects/esp-idf/en/latest/esp32/get-started/establish-serial-connection.htm l#check-port-on-windows

Wenn wir das alles vorbereitet haben, starten wir die Flashsoftware "Flash Download Tool". Wählt im

Last update: 2024/12/31 howtos\_knowledge\_base:loxberry\_wetterstation:3\_software:esp32 https://wiki.loxberry.de/howtos\_knowledge\_base/loxberry\_wetterstation/3\_software/esp32?rev=1735657380 16:03

Startscreen euren ESP32 aus (wenn er nicht gelistet ist, wählt ESP32) und setzt die Software auf Develop:

<	×		-	DOWN
2		2	ESP3	hipType:
/	~	lop	Deve	VorkMode:
^	~		UART	oadMode:
			ОК	
			ОК	

Oben wählt ihr als erstes das Firmware-File aus, welches ihr flashen wollt. Nutzt ihr die fertig kompilierten Firmwares des ESPEasy Projekts, geht ihr dazu in das bin-Verzeichnis der entpackten ESPEasy-Firmware und sucht Euch die collection\_G heraus. Diese beinhaltet alle Plugins die wir benötigen (aber eben ohne den Blitzsensor AS3935). Ihr müsst das **Factory**-File passend für euren ESP32 auswählen, also z. B.

ESP\_Easy\_mega\_20241222\_collection\_G\_ESP32\_4M316k.factory.bin. Wenn ihr die selbst kompilierte Firmware nutzen wollt, dann findet ihr die gerade kompilierte Firmware im Verzeichnis build\_output\bin. Auch hier müsst ihr das **Factory**-File auswählen.

Setzt vorne den Haken und gebt hinten als Startadresse hinter dem @-Zeichen 0x0 ein. Den SPI-Mode setzt ihr noch auf D0UT und wählt ganz unten den korrekten COM-Port aus, also z. B. C0M3. Danach klickt ihr auf START und der Flashvorgang sollte starten. Er dauert ungefähr 2 Minuten.

Das war's. Macht jetzt im Kapitel Konfiguration weiter.

### Konfiguration

Zieht den ESP32 vom USB ab und installiert und startet dann PuTTY. PuTTY stellt ihr auf eine Serielle Verbindung ein und gebt den COM-Port an, der eurem ESP32 von Windows zugewiesen wurde. Die Geschwindigkeit stellt ihr auf 115200. Last update: 2024/12/31 howtos\_knowledge\_base:loxberry\_wetterstation:3\_software:esp32 https://wiki.loxberry.de/howtos\_knowledge\_base/loxberry\_wetterstation/3\_software/esp32?rev=1735657380 16:03

Nun verbindet ihr den ESP32 wieder mit dem Rechner, wartet 1-2 Sekunden, bis der ESP erkannt wurde und klickt in PuTTY dann auf Open. Ihr solltet nun in PuTTY die Bootmeldungen des ESP32 sehen und er sollte das WLAN zur Erstkonfiguration aufmachen - die Meldungen sollten in etwa so aussehen und Euch die SSID des AP sowie die temporäre IP-Adresse des ESP32 mitteilen:

```
🖉 COM3 - PuTTY
                                                                           \times

```

Der ESP macht wie üblich ein eigenes WLAN auf - der Name variiert je nach Firmware etwas (siehe oben - ihr seht den Namen in den Bootmeldungen). Er lautet ESP\_Easy, ESPEasy, ESP\_Easy\_Collection\_G, lbweatherstation oder ähnlich. Das WLAN-Passwort ist configesp.

Verbindet Euch mit dem WLAN und konfiguriert euer eigenes WLAN wie üblich. Anschließend startet der ESP neu und verbindet sich mit eurem eigenen WLAN. Wie immer findet ihr in eurem Router die IP-Adresse des neuen Gerätes heraus. Ruft die IP-Adresse in eurem Browser aus.

Unter Config vergebt ihr nun einen Unit-Namen (Hostnamen) und eine Unit-Nummer. Die Unit-Nummer ist beliebig, sollte aber eindeutig sein - sie dient der Kommunikation verschiedener ESPEasy Installationen untereinander. Wir nutzen dieses Feature allerdings nicht weiter. Vergebt ein Admin-Passwort für das Webinterface. Der Zugang ist dann durch den User admin mit passendem Kennwort geschützt. Den Rest lasst ihr hier auf den Standardeinstellungen.

ESP Easy Mega:	Ibweatherstation_1
:Main OConfig	Controllers + Hardware V Devices + Tools

Im Tab Tools öffnet ihr nun noch unter System die Advanced Options. Unter Time Source aktiviert ihr NTP und nutzt den NTP-Server de.pool.ntp.org. Prüft die DST Settings (Sommer-/Winterzeit) und die Location Settings (hier die Timezone Offset (UTC +)). Unter Special and Experimental Settings aktiviert ihr noch Restart WiFi Lost Conn, damit der ESP die WLAN-Verbindung automatisch neu aufbaut, wenn er sie verliert. Im Tab Controllers fügen wir einen neuen Controller hinzu (bzw. editieren den bereits unter 1 angelegten Controller). Controller dienen der Kommunikation - wir richten hier unseren MQTT Broker ein. Als Protokoll wählt ihr Home Assistent (openHAB) MQTT aus und gebt die IP-Adresse und Port eures MQTT Brokers ein (normalerweise die IP-Adresse euer LoxBerry und Port 1883). Weiter unten unter Credentials aktiviert ihr Use Extended Credentials und gebt User und Passwort für euren MQTT Broker ein. Die notwendigen Einstellungen findet ihr im LoxBerry im MQTT Widget. Unter MQTT setzt ihr nun noch folgende Einstellungen:

- Controller Subscribe: %sysname%/sensors/#
- Controller Publish: %sysname%/sensors/%tskname%/%valname%
- Controller LWT Topic: %sysname%/status
- LWT Connect Message: running
- LWT Disconnect Message: stopped
- Send LWT to Broker: Ja
- Enabled: Ja

### ×

Anschließend sollte sich der ESP mit eurem MQTT Broker verbinden. Prüft den Status im Config Tab (gebt ihm ein paar Sekunden um sich zu verbinden).

Unter Hardware konfigurieren wir nun noch das I2C Interface und unsere GPIOs, die wir verwenden wollen. Zunächst konfigurieren wir unter I2C Interface die beiden GPIOs für SDA und DCL:

- GPIO SDA: GPIO-21
- GPIO SCL: GPIO-22

Danach setzen wir noch die GPIOs, die wir als digitale Eingänge verwenden wollen, als Eingang mit aktiviertem PullUp-Widerstand:

- GPIO-25: Input pullup
- GPIO-26: Input pullup
- GPIO-27: Input pullup
- GPIO-33: Input pullup
